

KASE Bond Actions

Coupon. Redeem. Vote.
Built on Solana.

Historical ownership determines coupons.
Escrow guarantees principal payment and bond retirement.

October 2026

Turn bond ownership into verifiable corporate actions

Record-date ownership

A current balance cannot tell an issuer who held bonds when a coupon became due.

Accurate entitlements

Calculate each holder's coupon and principal using exact integer token amounts.

Enforceable settlement

Record claims and retire redeemed bonds so an investor cannot receive principal twice.

The goal: Identify holders → Calculate entitlements → Settle → Record the outcome on Solana.

Reuse the app. Add enforceable settlement.

One Fastify backend, one Preact frontend, one Anchor program. No new database or indexer.

01

Historical ownership

Solana Index queries registered wallets at a finalized record-date slot.

02

Calculation & evidence

Integer entitlements, Merkle proofs, and canonical manifests stored through S3/IPFS.

03

Solana settlement

Token-2022 bonds and DEMOUSD. Anchor controls claims, escrow, burns, and payments.

04

Wallet experience

Privy login and wallet-signed transactions. Existing signed, weighted voting is retained.

Ownership at the record date earns the coupon

Face value 1,000 DEMOUSD $\times$ 10% annual rate $\div$ 2 periods = 50 DEMOUSD per bond.

500

Investor A · 10 bonds

10 $\times$ 50 DEMOUSD, based on historical ownership.

250

Investor B · 5 bonds

5 $\times$ 50 DEMOUSD, based on historical ownership.

100

Investor C · 2 bonds

2 $\times$ 50 DEMOUSD, based on historical ownership.

850 DEMOUSD total. Fund the vault, commit the Merkle root, then claim once per investor.

No principal payment without bond retirement

Actual escrow positions determine entitlement. Historical wallet balances do not authorize principal.

01

Lock the bonds

Investors deposit before cutoff. Each confirmed transfer increases their on-chain position.

17 bonds locked

02

Finalize settlement

After cutoff and maturity, reconcile escrow and fund the immutable principal liability.

17,000 DEMOUSD funded

03

Burn and pay atomically

Each investor redeems their full position. A failed burn or payment rolls back the transaction.

17 bonds burned

Signed voting. Immutable result commitment.

Existing voting is reused. Solana records the final commitment; it does not independently tally votes.

01

Snapshot voting power

Solana Index historical bond balances determine each investor's vote weight.

02

Signed voting receipts

Investors sign Approve, Reject, or Abstain. One vote per wallet, with IPFS evidence.

03

Canonical final tally

After voting closes, the backend aggregates exact weights and publishes a result manifest.

04

Issuer commitment

The issuer records proposal, snapshot, result, and evidence hashes on-chain once.

Three investors. One complete bond lifecycle.

Initial controlled distribution: A holds 10 bonds, B holds 5, and C holds 2.

17

Token-2022 bonds

KDB26 has zero decimals and a sealed initial issuance.

850

DEMOUSD coupon liability

50 DEMOUSD per bond for a semiannual coupon.

17,000

DEMOUSD principal liability

1,000 DEMOUSD per bond, settled against actual locked quantities.

Additional action: bondholder voting with historical weights of 10 / 5 / 2.

Demo targets, not independently verified totals for the current shared public deployment.

Historical balances without a new indexer

Solana Index supplies wallet + bond mint + slot balances. API credentials remain server-side.

Existing API client

HISTORICAL BALANCE /solana/devnet/token-balance/:wallet/:mint/:slot

FINALIZED SLOT RPC finality + Index slot history

RECORD TIME Disclose previous-block resolution

TOKEN INFO /solana/devnet/token-info/:mint

Registry totals must reconcile to 17 bonds

Illustrative historical response

```
{
  "balanceRaw": "10",
  "decimals": 0,
  "slot": "RECORD_SLOT",
  "address": "INVESTOR_A",
  "token": "BOND_MINT"
}
```

Illustrative fields; not a captured live API response

Built locally. Available to review on devnet.

Local verification and public integration are reported separately.

Implemented and locally tested

- Historical snapshot parsing and Merkle proofs
- Coupon authorization and duplicate prevention
- Escrow deposits and atomic burn/payment
- Signed weighted voting and result commitments
- Frontend flows with mocked wallet/API sessions

3

Corporate actions

17

Demo bonds

Controlled initial issuance.

A clear prototype boundary

DEMOUSD is a mock token. This is not audited securities or production custody infrastructure.

Data and registry trust

- The issuer manages the holder registry; Solana Index does not enumerate all holders.
- The backend checks completeness against expected issuance.
- A Merkle root proves membership, not the correctness of historical data.

Verification and production work

- Local tests mock historical APIs, S3/IPFS, and wallet extensions.
- The complete live browser lifecycle still requires separate verification.
- Bundled demo keys are public; the upgrade authority can replace program logic.
- Production needs audit, governed authorities, recovery, issuance controls, and legal settlement rails.

Settlement and voting limits

- Bonds outside escrow cannot be forcibly retired.
- Escrow has no withdrawal or recovery instruction.
- Signed votes are tallied off-chain; the chain stores the issuer's result commitment.

TRY THE
PROTOTYPE

Historical coupons. Atomic redemption.

A focused demonstration of tokenized bond corporate actions on Solana, powered by Solana Index.
